

Termination Analysis for Multi-Path Linear Loops

Hui Jin et. al from Tianjin Uni.

July 14, 2020

History of Research

Joint research with Xiaofei Xie of NTU.

- ▶ Xiaofei Xie, Bihuan Chen, Liang Zou, Shang-Wei Lin, Yang Liu, and Xiaohong Li. “Loopster: static loop termination analysis.” In Proceedings of the 2017 11th Joint Meeting on Foundations of Software Engineering, pp. 84-94. ACM, ESEC/FSE 2017

Contribution

- ▶ Extend the path dependency automaton(PDA) to analyze the linear loop and extract paths in CFG as states in the PDA to obtain the dependency relationship between paths.
- ▶ Make a simple classification of cycles in PDA, and proposed methods to determine the termination of the cycle.
- ▶ Implement algorithm proposed by Tiwari to determine the termination of linear loops.

Loop Path of CFG

Definition (Control Flow Graph(CFG))

A control flow graph of a loop is a tuple $\mathcal{G} = (V, E, v_s, V_h, V_e, 1)$, where V_h, V_e are the set of header blocks and exit blocks respectively. $1(e)$ is the branch condition of the edge $e \in E$.

Definition

Given a CFG $\mathcal{G} = (V, E, v_s, V_h, V_e, 1)$, the loop path σ is a finite sequence v_0, v_1, \dots, v_k of basic blocks where $v_0 \in V_h$ and $v_k \in V_h \cup V_e$ are the head and tail of σ . We call a path iterable path if $head(\sigma) = tail(\sigma)$.

- ▶ Path condition: θ_σ is the conjunction of the branch condition of each edge in the path.
- ▶ Value change of vars: \mathcal{V}_σ . $\theta(\sigma_i, \mathcal{V}_{\sigma_j}^n) \rightarrow \{true, false\}$.
- ▶ $pre(\mathcal{G})$: precondition of loop represent the possible valuation of vars.

Exmaple

```
int x = *;  
int y = *;  
  
while (2x+y>0) {  
    if (y>0) {  
        x = -x-y;  
        y = -3y;  
    } else {  
        x = -2x+y;  
    }  
}
```

Loop paths: $\sigma_1 = (b, c, e, b)$, $\sigma_2 = (b, c, f, b)$, $\sigma_3 = (b, d)$

Path Dependency Automaton

Definition (Path Dependency Automaton(PDA))

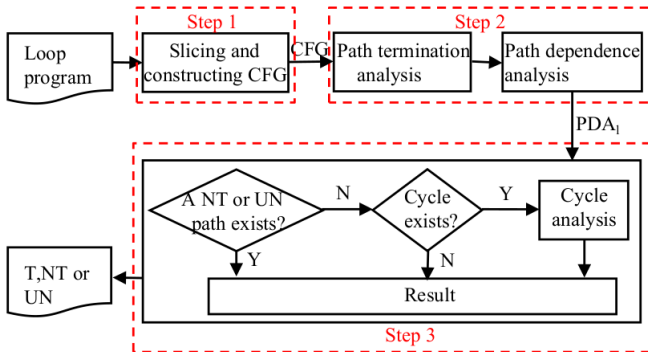

Given a loop with CFG \mathcal{G} , the path dependency automaton of this loop is $\mathcal{A} = (S, T, init, accept)$ where

- ▶ S is the set of states. Each $\sigma \in S$ corresponds to a path in the loop.
- ▶ $T \subseteq S \times S$ is a set of transitions. $(\sigma_i, \sigma_j) \in T$ means that $\exists n > 0$ s.t. $\theta(\sigma_j, \mathcal{V}_{\sigma_i}^n) = true \wedge tail(\sigma_i) = head(\sigma_j)$.
- ▶ $init, accept$ are the set of initial states and accepting states respectively.

Example

Overview of MLTERM

The main part of termination analysis is step 3, where we first check if there is NT or UN path reachable. If not, do cycle analysis.

Path Termination Analysis

If the path is not iterative, it is terminating.

Otherwise the path represents a loop.

$$\text{while}(Bx > 0)\{x = Ax\}$$

Do termination analysis on this loop and output T if it is terminating.

The method for the terminating analysis is from [Tiwari].

[Tiwari] Termination of Linear Program.

Algorithm 1 PathTermAnalysis($\sigma, pre(\sigma)$)

Input: $\sigma, pre(\sigma)$: the precondition of σ

Output: $\{T, NT, UN\}$

```
1: for all  $\sigma \in S$  do
2:   if  $head(\sigma) \neq tail(\sigma)$  then
3:     return  $T$ 
4:   end if

5:   Construct while  $Bx > b$  do  $x = Ax + c$  to analysis
   termination of  $\sigma$  denote as term
6:   if term =  $T$  then
7:     return  $T$ 
8:   else
9:     if  $pre(\sigma) = true$  then
10:      return  $NT$ 
11:    end if
12:    if  $pre(\sigma)$  always satisfiable in  $\sigma$  then
13:       $\sigma.condition.append(pre(\sigma))$ 
14:      return PathTermAnalysis( $\sigma, true$ )
15:    end if
16:    return  $UN$ 
17:  end if
18: end for
```

Examples

```
int x=*;  
int y=*;  
while(x>0 && y>0) {  
    x = x-y;  
    y = y-1;  
}
```

(a) T

```
int x=*;  
int y=*;  
while(x>0) {  
    x = x-y;  
    y = y-1;  
}
```

(b) NT

```
int x=*;  
int y=*;  
if(y>0) {  
    while(x>0) {  
        x = x-y;  
        y = y-1;  
    }  
}
```

(c) UN

(b) NT with witness $x = 2, y = 1$. (c) $pre(\mathcal{G})$ is not always satisfied.

Path Dependence Analysis

Target of path dependence analysis is to determine whether a loop path can transit to another.

There are two kinds of transitions:

- ▶ σ_i is terminating and its outdegree is 1.
- ▶ Check whether the formula $\exists n. \theta(\sigma_j, \mathcal{V}_{\sigma_i}^n)$ is *true*.

Algorithm 2 ComputeTran(\mathcal{G})

Input: $\mathcal{G} : CFG$

```
1: for all  $(\sigma_i, \sigma_j) \in \{(\sigma_m, \sigma_n) \mid \sigma_m \in S \wedge \sigma_n \in S \wedge tail(\sigma_m) = head(\sigma_n) \wedge m \neq n\}$ 
   do
2:   if  $\sigma_i$  is termination  $\wedge \sigma_i.outdegree = 1$  then
3:      $T = T \cup ((\sigma_i, \sigma_j))$ 
4:   else
5:     if  $\theta(\sigma_j, \mathcal{V}_{\sigma_i}^n) == true$  then
6:        $T = T \cup ((\sigma_i, \sigma_j))$ 
7:     end if
8:   end if
9: end for
```

Cycle Analysis

Definition (Cycle in PDA)

Let $\mathcal{C} = \{\sigma_1, \sigma_2, \dots, \sigma_n\}$. \mathcal{C} is a cycle of PDA if

- ▶ $\mathcal{C} \subset S$
- ▶ $\sigma_1, \sigma_2, \dots, \sigma_n$ constitutes an SCC in PDA.

Classify cycles into 2 categories:

- ▶ Type 1 cycle: All path in \mathcal{C} are one-time paths.
- ▶ Type 2 cycle: Otherwise.

Cycle Analysis for Type 1

Idea: Since all paths are simple, we can simply merge them into a new path and do path termination analysis on the new path.

```
1: if  $\forall \sigma_i \in \mathcal{C} \wedge \sigma_i.iterable = false$  then  
2:    $\sigma = \text{merge}(\mathcal{C})$   
3:   return PathTermAnalysis( $\sigma, pre(\sigma_1)$ )  
4: end if
```

Cycle Analysis for Type 2

assume \mathcal{C}_{II} is a set that all iterable path in \mathcal{C}

```
5: for all  $\sigma \in \mathcal{C}$  do
6:   if  $head(\sigma) == tail(\sigma)$  then
7:      $\mathcal{C}_{II}.append(\sigma)$ 
8:   end if
9: end for
10: for all  $\sigma \in \mathcal{C}_{II}$  do
    We use  $\Theta_\sigma$  to denote the conditional of  $\sigma$ 
11:   if  $\exists \theta_i \in \Theta_\sigma$  only change in  $\sigma$  then
12:      $\mathcal{C}.del(\sigma)$ 
13:      $\mathcal{C}_{II}.del(\sigma)$ 
14:   end if
15: end for
16: if  $\mathcal{C}$  is not a cycle then
17:   return  $T$ 
18: end if

19: if  $\mathcal{C}_{II}.empty()$  then
20:   return  $CycleAnalysis(\mathcal{C})$ 
21: end if
22: return  $UN$ 
```
